## Advantage

- ▶ Cheap
- ▶ Easy to get
- ▶ Flexible to complicated environments

## Disadvantage

- ▶ Not as accuracy as depth sensor
- ▶ Need a lot of calculate power
- ▶ Need a lot of training
- ▶ Not stable in current time

## Advantage

- ▶ Cheap
- ▶ Easy to get
- ▶ Flexible to complicated environments

## Disadvantage

- ▶ Not as accuracy as depth sensor
- ▶ Need a lot of calculate power

# Related Work: Use Traditional Ways

In the traditional way of doing obstacle avoidance task, one should use the camera to detect the point flow to get the information about the environment. For example, the position of the floor and obstacles. Then we can use some fixed way to plan and executes.

- ▶ Use Depth camera to get Point Cloud
- ▶ Use the Point Cloud to fitting a function about the ground
- ▶ Calculate the distance between every point with the fitting ground  $h$
- ▶ If  $h$  is larger than a setting threshold, then marke it as an obstacle
- ▶ Transfer the Point Cloud data of the obstacle to the robot coordinate space
- ▶ Combine the current robot moving stats with the obstacle to decide how to avoid the obstacles

# Related Work: Use Traditional Ways

# Use Reinforcement Learning: Q-Learning

The mission of RL is to find a *best policy* in order to make the reward more.

The value function(Bellman Function) describes how to get the value of current state, that is,

$$V(s) = \mathbb{E}[R_{t+1} + \lambda v(S_{t+1}) | S_t = s]$$

To update the Q value, that is,

$$Q(S_t, A_t) \leftarrow Q(S_t, A_t) + \alpha(R_{t+1} + \lambda \max_a Q(S_{t+1}, a) - Q(S_t, A_t))$$

# Use Reinforcement Learning: Q-Learning

The mission of RL is to find a *best policy* in order to make the reward more.

The value function(Bellman Function) describes how to get the value of current state, that is,

$$V(s) = \mathbb{E}[R_{t+1} + \lambda v(S_{t+1}) | S_t = s]$$

To update the Q value, that is,

$$Q(S_t, A_t) \leftarrow Q(S_t, A_t) + \alpha(R_{t+1} + \lambda \max_a Q(S_{t+1}, a) - Q(S_t, A_t))$$

# Use Reinforcement Learning: Q-Learning

The mission of RL is to find a *best policy* in order to make the reward more.

The value function(Bellman Function) describes how to get the value of current state, that is,

$$V(s) = \mathbb{E}[R_{t+1} + \lambda v(S_{t+1}) | S_t = s]$$

To update the Q value, that is,

$$Q(S_t, A_t) \leftarrow Q(S_t, A_t) + \alpha(R_{t+1} + \lambda \max_a Q(S_{t+1}, a) - Q(S_t, A_t))$$

# Use Reinforcement Learning: DQN

In the Q-Learning we give a Q table:

	$a_1$	$a_2$	$a_3$	$a_4$
$s_1$	Q(1,1)	Q(1,2)	Q(1,3)	Q(1,4)
$s_2$	Q(2,1)	Q(2,2)	Q(2,3)	Q(2,4)
$s_3$	Q(3,1)	Q(3,2)	Q(3,3)	Q(3,4)
$s_4$	Q(4,1)	Q(4,2)	Q(4,3)	Q(4,4)

Due to store too many states in one Q table is unrealistic in DQN, we get Q table from a network.

# Use Reinforcement Learning: DQN

In the Q-Learning we give a Q table:

	$a_1$	$a_2$	$a_3$	$a_4$
$s_1$	Q(1,1)	Q(1,2)	Q(1,3)	Q(1,4)
$s_2$	Q(2,1)	Q(2,2)	Q(2,3)	Q(2,4)
$s_3$	Q(3,1)	Q(3,2)	Q(3,3)	Q(3,4)
$s_4$	Q(4,1)	Q(4,2)	Q(4,3)	Q(4,4)

Due to store too many states in one Q table is unrealistic in DQN, we get Q table from a network.

# Use Reinforcement Learning: Get Reward

```
def get_reward(self, action):  
    if self.flag == action:  
        if action == 0:  
            reward = 1  
        else :  
            reward = 0  
    else :  
        reward = -1  
    return reward
```

Flag is whether the robot is crashed a bumper. In the future, we need to add more actions.
