Table of Contents

- 1 Recap
- 2 LGAfford-Net
- 3 CoPa
- 4 Demo
- 5 Conclusion

3D Affordance Detection

- Complex manipulation tasks require fine-grained object understanding
- 3D Affordance Detection Task
 - Input: 3D representation of objects/environment
 - (+ Textual Prompt)
 - Output: Affordance labels for individual regions
- Affordance vocabulary types
 - Closed \Rightarrow Predefined set of labels
 - Open \Rightarrow Ranging from unseen labels to complex freeform instructions

Figure: Example affordance labels¹

¹Nguyen et al., IROS 2023

Overview

- Legacy approaches offer limited generalizability
 - Affordance vocabulary
 - Object types
- Recent approaches leverage pre-trained foundation models
 - Task-oriented scene understanding
 - Open-set textual task understanding
 - Object part segmentation
 - Grasp pose candidate generation
- Challenges
 - Affordances depend on robot setup
 - Incomplete information

LGAfford-Net²

- Closed-vocabulary approach
- Trained on 3D AffordanceNet dataset
- Emphasis on local geometry

²Tabib et al., CVPR 2024

Semantic Geometric Correlator

- P - Input Point Cloud
- ϕ - Local Geometric Features
- P_L - Learned Local Geometric Features
- S - Semantic Local Geometric Features

Local Geometric Descriptor

- Create triangles from each point $p_i \in \mathbb{R}^n$ and two nearest neighbors p_{j_1}, p_{j_2}
- Gather into higher-dimensional descriptor vector:

$$\phi_i = \begin{cases} p_i \\ \vec{e}_1 = p_{j_1} - p_i \\ \vec{e}_2 = p_{j_2} - p_i \\ |\vec{e}_1| \\ |\vec{e}_2| \\ \hat{n} = \vec{e}_1 \times \vec{e}_2 \\ \mu_i = \text{mean}(p_j) \\ \sigma_i = \text{std}(p_j) \end{cases}$$

Edge Convolution³

K-Nearest-Neighbor

Edge Convolution

- \mathcal{S} - Semantic Local Geometric Features

- $\mathcal{S}_i = \max_{x_j \in \mathcal{K}_S} [h_\theta(x_j - x_i, x_i)]$

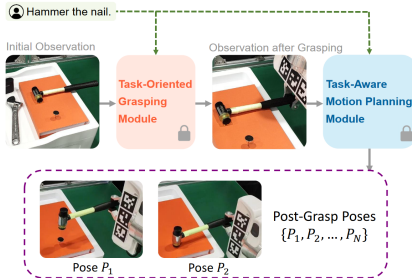

³Wang et al., ACM TOG 2019

Class-Specific Classifier

- Train independent classifiers per affordance category
- Output for each point: Probability scores of all affordance categories

CoPa⁴

- Open-vocabulary approach
 - Textual task specification
- Utilize foundation models for affordance detection
- Outputs sequence of 6-DoF poses

⁴Huang et al., IROS 2024

Grounding Module

- Set-of-Mark (SoM)⁵ prompting for VLM
 - Segment image and assign numeric markers
- Coarse: Find graspable object in scene
- Fine: Find graspable part of object

⁵Yang et al., arXiv, 2023

Task-Oriented Grasping Module

- Pose candidate generation using GraspNet⁶
- Select highest-confidence candidate within grasping part mask

⁶Fang et al., CVPR 2020

Task-Aware Motion Planning Module

Current Observation

Find task-relevant geometry parts.
Hammer the nail.

Grounding Module
3D Processing

Task-Relevant
3D Components

Constraint
Generation

Spatial Constraints:

1. **Vector 2** and **Vector 3** are colinear.
2. **Point 2** is 5 cm above **Point 3**.
3. **Vector 2** points downward.
4. **Vector 1** is parallel to the table surface.

Subsequent Actions:

1. Move vertically down 7 cm.

Solver

Post-Grasp Poses
 $\{P_1, P_2, \dots, P_N\}$

- Task-relevant part grounding
- Manipulation constraint generation
 - Overlay simplified geometric indicators (vectors, surfaces)
 - Describe spatial constraints and action sequence using VLM
- Target pose planning
 - Nonlinear constraint solver
 - Sequentially compute post-grasp poses

Demo

Summary

- Emergence of foundation models has strongly impacted 3D affordance detection
- CoPa can easily be integrated into higher-level planning frameworks
 - Perform complex multi-step tasks
 - Explore unknown information
 - Adapt to dynamic scene changes

Limitations & Future Work

- Current challenges and limitations
 - Vector/surface constraint modeling is not sufficient for all object types and manipulation tasks
 - Spatial reasoning capabilities of VLMs are limited because of a lack of representation in input data
- Future research directions
 - Refine geometric constraint modeling
 - Incorporate RGB-D data into VLM training
